Notes:

MTTF = Mean Time To Failure

MTBF = Mean Time Between Failures (includes repairing)

MTTF value can be used in practise for relays because repairing time is short.

MTTF value is used to predict the reliability of the system.

Expected life for relays depends on the life of the electrolytic capacitor or other components which have limited life.

MTTF values for input relays are calculated in conditions, which the relays are assembled in the mounting base side by side, all relays in on-state, the input voltage is nominal and ambient temperature is 25 °C.

MTTF values for output relays are calculated in conditions, which the relays are assembled in the mounting base side by side, all relays in on-state, the input voltage is nominal, the ambient temperature is 25 °C and the load is 50 % of maximum and resistive.

For GL-relays in the table are same values than is calculated for nearest SL-versions. The values can be used for calculations depending on how the GL-relays are assembled.

MTTF values are calculated adapting MIL-HDBK-217F standard.
